

#3: City Fleets

CORE METRIC FOR CATEGORY A & B & C CITIES

Bold, green font indicates metrics that must improve to be recognized at Step 5

- **City Vehicles:**
 - 3.1 Vehicle miles traveled (VMT) for gasoline fleet
 - 3.2 Average miles per gallon (MPG) for gasoline fleet**
 - 3.3 Vehicle miles traveled (VMT) for diesel fleet
 - 3.4 Average miles per gallon (MPG) for diesel fleet**
 - 3.5 Number of electric vehicles in city fleet

METRIC DEFINITION

- **Fleet vehicles** include city-owned and -leased utility vehicles, cars, vans, trucks, and heavy equipment, such as those used in snow plowing, street sweeping, earth-moving, and construction. Include police cars, other emergency vehicles, and NEVs (neighborhood electric vehicles: battery electric vehicles with a top speed of 25 MPH and which, while usually used by parks departments, can be driven on public roads). Also include data from city-employee-owned vehicles used for city business for which the city reimburses employees. Transit and school buses are generally excluded because they are not fully owned and controlled by city government. ([Metrics 3.1-3.5](#))
- **A city's fleet is divided** for the purposes of this metric into gasoline, diesel-fueled, and electric vehicles. Typically these are distinct fleets: passenger cars, heavy-duty vehicles, and full-electric cars, with widely divergent average miles per gallon efficiency. ([Metrics 3.1-3.5](#))
- **Vehicle miles traveled for the gasoline fleet** includes those miles driven by hybrid electric vehicles, exclude miles driven in full-electric vehicles, and include those miles driven by CNG (compressed natural gas) vehicles. ([Metric 3.1](#))
- **Average miles per gallon for gasoline fleet** is a simple calculation done by adding gallons of standard gasoline (E10), E85, other ethanol blends, and CNG gasoline gallon equivalents, not adjusted (normalized) for the differing energy content of these different fuels (unless a city wishes to do this calculation). ([Metric 3.2](#))
- **Average miles per gallon for the diesel fleet** is not adjusted (normalized) for the differing energy content of standard diesel (B10) and other blends (unless a city wishes to do this calculation). The gallons of different blends should all be added together. ([Metric 3.4](#))
- **Electric Vehicles** are owned and leased vehicles where the drive-train is powered exclusively by an electric motor. This would include NEVs and all electric vehicles such as the Nissan Leaf. ([Metric 3.5](#))

DATA SOURCES

- City fleet data ([Metrics 3.1-3.5](#))
- City administration, public works, and parks departments ([Metrics 3.1-3.5](#))

METRIC CALCULATION AND PUBLIC REPORTING

- **VMT for the city's gasoline and diesel fleets** are total miles driven during the calendar year preceding the reporting year, by various vehicles as defined in the Metric Definition. ([Metrics 3.1 and 3.3](#))

- **MPG for the city's gasoline and diesel fleets** are calculated as follows: divide gasoline fleet VMT by total gallons of gasoline used, and divide diesel fleet VMT by total gallons of diesel used. For gallons of CNG used, use the 1994 NIST standard of 5.66 pounds of natural gas per gallon of gasoline. ([Metrics 3.2 and 3.4](#))
- **For electric vehicles**, report the number owned or leased by the city as of the December 31st preceding the reporting year. ([Metric 3.5](#))

METRIC RATIONALE

Tracking miles driven and gallons used is widespread and simple to do for two generally distinct vehicle categories. The two resulting measures are simple ones for city leaders and tax payers to track. Improvements in MPG represent cost and energy savings and fewer air emissions from improved vehicle efficiency and improved fuels. In simplifying the MPG average calculation by not counting the gallon-equivalent energy content of different liquid fuels and electricity for charged hybrids (but using CNG gasoline gallon equivalents), phasing in of more energy efficient vehicles is incentivized by the resulting higher MPG numbers.

Electric vehicles are tracked separately, as their superior technology converts 59%–62% of the electrical energy from the grid to power at the wheels, as opposed to the inefficiency of conventional gasoline vehicles that convert only 17%–21% of the energy stored in gasoline to power at the wheels.

STEP 5 METRIC TARGETS

Individual cities are best equipped to set realistic goals for metric improvement, and any improvement in the metrics is good. That said, the State of Minnesota has the following goal:

- Reduce state fleet consumption of fossil fuels by 30% by 2027 relative to a 2017 baseline. A 5% annual reduction in city fleet fossil fuel consumption is consistent with this state agency operations goal.
